

Program description :

I created a file for the teacher to add the names of students ,classes, sections and Id, in addition to the possibility of modifying the student data entered ‘ The data will be returned‘ In addition to the possibility of deleting a student

Program requirements :

- Create file.
- while loop .
- if .. else if .. else statements.
- foreach .. break .

Requirement Describe :

- I created a text file in order to show me the output while running the program and writing inside it..
- while loop .. The while loop is executed at least once because it checks the condition after the commands are executed and not before them. And it repeats a certain process or several operations as long as the condition is true
- else if .. else ... - We use it to solve programming problems that depend on conditions. There is a set of commands that are executed only when a condition is met. It is used to test and verify a condition, so it is an important programming tool.
- The foreach construct provides an easy way to move between array elements. It works only with arrays and objects. Using it with a variable of a different data type or an uninitialized variable throws an error.
